Pesly — Financial Intelligence for Vehicle-Based Work

Revised Business Plan (v2)

1. Executive Summary

Pesly is a technology company building an intelligent financial and operational platform for drivers and vehicle owners in the mobility and delivery economy.

The platform automatically gathers available evidence from trips, vehicle activity, platforms, financial transactions and expenses; reconciles conflicting information; calculates vehicle and driver economics; and converts the resulting data into actionable intelligence.

The fundamental problem Pesly solves is simple:

Drivers and vehicle owners often do not have one trustworthy picture of what a vehicle actually earned, what it cost to operate, where money was lost, and why performance changed.

Today, information is fragmented across:

- ride-hailing platforms
- delivery platforms
- M-Pesa
- fuel purchases

- receipts
- spreadsheets
- WhatsApp
- driver memory
- owner records
- GPS/telematics systems

Pesly brings those fragments together.

Its core philosophy is:

Collect evidence → reconcile reality → explain it → create intelligence.

Pesly will initially focus on automated earnings and cost reconciliation, then expand into broader fleet intelligence, predictive maintenance, optimization and eventually financial services.

1.5 Founding Team

Pesly is currently founded and led solo by **Angela Odhiambo**.

- **Background:** Bachelor of Science in Computer Science (University of the People), with a working career as a Frontend Developer / UI/UX Designer — currently a UI/UX Design Intern at FlyRank AI.
 - **Relevant prior experience:** Customer Value Management (CVM) Analyst, focused on customer data analysis and segmentation — directly applicable to the kind of pattern-matching, anomaly-flagging, and segmentation logic Pesly’s reconciliation and intelligence engines depend on.
 - **What this covers today:** product design, the driver/owner experience layer (Section 7.6–7.7), UX for the evidence model, and the overall reconciliation logic design.
 - **What this doesn’t cover yet:** Pesly does not yet have a dedicated backend engineer. Pesly is intentionally staying single-founder for now, so building the ledger, reconciliation engine, and financial engine (Sections 7.3–7.4) at production quality will be funded through contracted backend development (Section 36’s pilot budget) rather than a co-founder hire. A technical co-founder remains an option to revisit later if the workload requires it.
-

1.6 Company Formation & Grant Eligibility

Pesly is not yet a registered legal entity. This is stated plainly rather than assumed away, because eligibility rules on this point vary significantly between funding programs and directly affect timing.

What’s generally true across idea-stage funding in Kenya and the wider region: informality is one of the most common reasons applications don’t proceed past initial screening, so registration is worth treating as a “when,” not an “if.” But the specific timing requirement differs by program — some funders explicitly allow applying

while unregistered and only require formal registration before funds are disbursed (a common pattern for non-dilutive, idea-stage grants), while others require registration as a condition of entry. This means the right move is not to register speculatively before a target is chosen, but to have registration ready to execute quickly — in Kenya this runs through the Business Registration Service — once a specific program’s rules are known.

Before finalizing this section with a specific answer, two things still need to happen:

1. **Identify 2-3 target programs** and check each one’s actual eligibility page for: entity requirement and timing, company-age limits, ownership/citizenship conditions, and sector fit. One concrete example worth checking directly for fit is the MEST Africa Challenge, which is built specifically for tech entrepreneurs in Kenya and several other African countries and is aimed at software/platform businesses rather than physical products — a plausible fit for Pesly’s stage and sector, but not yet confirmed against its current rules.
2. **Decide registration type in advance** (e.g., private limited company under the Companies Act, 2015, which is the standard structure for a startup seeking investment or grant funding later) so that if a chosen program requires registration on short notice, that decision isn’t being made under deadline pressure.

This section is intentionally left as a to-do with a clear next step, rather than a confident claim about eligibility Pesly hasn’t verified yet — consistent with the plan’s own principle of treating unproven claims as hypotheses (Section 48).

2. The Problem

The mobility economy has an information problem.

A driver may know: “I made KSh 8,000.” An owner may know: “The vehicle brought in KSh 8,000.” The platform may show: KSh 7,300. The M-Pesa statement may show something else. Fuel may have cost: KSh 2,000. Data: KSh 300. Parking: KSh 400.

The owner may have a fixed daily arrangement. The driver may have paid the fuel. And nobody has a reliable answer to: **“What did this vehicle actually make?”**

That’s the gap Pesly addresses.

3. The Problem for Drivers

Drivers need to know:

- how much they actually earned
- how much platforms deducted
- how much they spent
- how much they gave the owner
- what their net earnings were

- which working periods are profitable
- whether their performance is improving
- whether reported figures are accurate
- what evidence exists when a dispute occurs

Most importantly: **drivers should not have to manually reconstruct their financial lives every evening.**

4. The Problem for Owners

Owners need to know:

- how their vehicles perform
- how much revenue each vehicle generates
- operating costs
- fuel efficiency
- utilization
- maintenance costs
- profitability
- unusual revenue/cost patterns
- whether reported figures reconcile with available evidence

The owner doesn't simply need "Where is my car?" — they need **"Is my vehicle economically healthy?"**

5. The Core Product

Pesly's initial product is **Automated Earnings Reconciliation.**

Pesly detects activity and gathers available evidence, then creates a reconciled financial picture.

Example — Vehicle KDA 123A

Line item	Amount
Gross revenue	KSh 8,400
Platform deductions	– KSh 1,200
Fuel	– KSh 1,800
Data	– KSh 300
Parking	– KSh 200
Other operating costs	– KSh 250
Net operating contribution	KSh 4,650

Pesly then applies the relevant owner-driver agreement to produce the appropriate driver and owner views. Every figure can be expanded to show its evidence.

6. Pesly's Fundamental Differentiator

Pesly does not simply collect reports. It reconciles them.

Example:

Source	Reported amount
Platform	KSh 820
Driver	KSh 850
Expected range	KSh 780-900

Pesly's output: "Platform evidence currently supports KSh 820. Driver-reported KSh 850 remains unverified."

That's the difference between recording information and creating trustworthy intelligence.

7. Product Architecture

The product consists of seven major layers.

7.1 Data Acquisition Layer

Connects to platforms, authorized financial sources, mobile/device signals, telematics, receipts, and user input.

This is the layer with the highest execution risk, so acquisition is deliberately tiered by legal safety and build effort — not all sources are treated as equally available on day one.

Tier 1 — MVP-ready, lowest legal risk

- **Email-based statement ingestion.** Uber and Bolt already send drivers periodic earnings statements by email. With driver OAuth consent (read-only Gmail API access, scoped to specific senders), Pesly auto-ingests these. The driver is authorizing access to *their own inbox* — not a third-party system — which keeps this on solid legal ground.
- **M-Pesa SMS parsing.** With explicit consent and Android SMS-read permission, Pesly parses payout confirmation texts (platform payouts, fuel till-number payments, etc.). This mirrors the approach already used by several African income-verification and lending apps, and is defensible because it's the user's own device data.
- **Manual quick-capture.** A photo/OCR of the in-app "trip summary" or "earnings" screen as a fallback for anything the above two miss. Slower, but zero legal ambiguity.

Tier 2 — corroboration, not revenue truth

- **Phone-sensor trip detection** (GPS + accelerometer, offline-first: capture → store locally → sync later). This independently estimates trip count, distance, and duration. It cannot tell Pesly what a trip *paid*, but it lets the reconciliation engine flag mismatches — e.g. “driver reported 14 trips, phone detected 9” — as an anomaly worth investigating.

Tier 3 — higher value, higher risk, deferred past MVP

- **Notification-listener capture** (reading in-app trip-completion notifications in near real time). Technically reads only the driver’s own device, but sits in a gray zone relative to platform terms of service and could put a driver’s account at risk if a platform decides to police it. Held as a future, legal-review-gated capability.
- **Formal platform partnerships / official API access.** A long-term goal that strengthens the reconciliation moat, but is an enterprise BD motion measured in years, not a pilot-stage dependency.

Pre-build step: before any Tier 1 development begins, Pesly will complete a short review of Uber’s and Bolt’s driver terms of service regarding email-forwarding/third-party financial tools, and of Safaricom’s terms on SMS-based parsing by consented apps, to confirm the acquisition methods above remain compliant as designed.

Platform scope — stated explicitly rather than left implicit. Of the three Tier 1 methods, two are platform-agnostic: email-based statement ingestion (Gmail OAuth works identically on Android and iOS, since it’s a server-side connection) and manual quick-capture (a photo works on any phone). Only M-Pesa SMS parsing is Android-specific — iOS restricts third-party apps from reading SMS content, so an iOS driver’s M-Pesa evidence would fall back to manual capture of the payment confirmation instead of automatic parsing. Given that Android holds roughly 90%+ of the smartphone market in Kenya, this is a deliberate, low-cost trade-off for the MVP rather than a blind spot — Pesly is effectively Android-first by design for its one automated-but-restricted data source, with iOS supported everywhere else from day one, and full iOS parity is a post-pilot decision rather than an MVP requirement.

7.2 Evidence Layer

Stores: source, timestamp, event, associated vehicle, associated driver, evidence type, confidence/provenance.

7.3 Reconciliation Engine

Compares: platform data, vehicle activity, driver reports, owner reports, financial records, historical patterns.

7.4 Financial Ledger

Maintains revenue, deductions, expenses, agreements, allocations, corrections, and disputes, with an immutable history.

7.5 Intelligence Engine

Provides anomaly detection, trend analysis, benchmarks, forecasts, and recommendations.

7.6 Experience Layer

Separate experiences for drivers, owners, fleet managers, and administrators.

7.7 AI Interface

Allows users to ask things like “Why did my net earnings fall?”, “Which vehicle is performing worst?”, “What expenses increased?” The AI explains the underlying data; it does not invent the financial facts.

8. The Pesly Evidence Model

Every important piece of information gets a status:

- **Verified** — strong independent evidence exists
- **Supported** — evidence exists but isn’t sufficient for full verification
- **Reported** — someone supplied the information
- **Estimated** — Pesly calculated a likely value
- **Disputed** — credible sources disagree
- **Unverified** — insufficient evidence
- **Reconciled** — Pesly has compared available evidence and produced the best-supported result

This becomes a foundational part of the product.

9. The Driver Product

The driver experience should be extremely simple.

Home

Today’s earnings: **KSh 5,240 net** 14 trips · 126 km · 6h 42m

Your money

Gross: KSh 7,800 Deductions: KSh 1,100 Operating costs: KSh 1,460 **Net earnings: KSh 5,240**

2 things need your attention

No overwhelming dashboards.

10. Driver Benefits

Pesly gives drivers:

- **Financial clarity** — know where their money went
- **Earnings optimization** — understand when and how they perform best
- **Protection** — evidence during disputes
- **Portable work history** — a persistent Pesly identity rather than a record controlled entirely by one fleet
- **Transparency** — see what Pesly knows
- **Privacy control** — see what owners can access

This is crucial: **Pesly must never feel like an owner-monitoring application installed on a driver's phone.**

10.5 Driver Data Cost & Retention Design

Data cost. The core problem Pesly solves is drivers losing money to fuel, data, and other small leaks — so Pesly's own data footprint has to be genuinely negligible, not just “offline-first” in principle. In Kenya, cheap data runs roughly KSh 20 for 250MB (daily bundle) or about KSh 50-99 per week for 100-350MB. If Pesly is built the way Section 7.1 and Section 25 already intend — batched trip summaries instead of raw GPS streaming, on-device OCR for photo capture instead of uploading full images to a server, and periodic (not continuous) statement sync — its own monthly footprint should realistically stay in the tens of megabytes, translating to roughly KSh 10-20/month. That number isn't proven yet, but it's a concrete engineering target the MVP should be held to and measured against during the pilot (Section 36's “data usage” metric), rather than an assumption left unstated.

Retention — why a driver opens Pesly after week one. Free removes the adoption barrier, but doesn't answer what brings a driver back once the novelty wears off. Three concrete mechanisms, tied to real utility rather than engagement tricks:

- **Pesly reaches the driver, not the other way around.** A weekly summary (net earnings this week vs. last week, in one line) pushed as a notification or WhatsApp message means the driver doesn't need to remember to open the app for the core value to land. This also matches Section 37's own success metric — *weekly* active drivers, not daily — so the product should be designed for a weekly rhythm rather than assuming daily engagement it doesn't need.
- **Flag-driven return, not artificial return.** A “2 things need your attention” notification (Section 9) only fires when there's a genuine reconciliation anomaly or dispute-relevant event — utility-driven re-engagement, not a manufactured streak or gamified hook.
- **The income-history payoff should arrive sooner than “eventually.”** Portable work history (Section 10) is only felt as valuable the day a driver needs proof of income for a loan — which could be months away. Pursuing at least one early lender or SACCO relationship during the pilot (Section 36) so a few drivers feel that payoff *during* the pilot, not after, would make retention self-reinforcing

much earlier than waiting for the “future revenue streams” stage (Section 31) to materialize it.

Why this matters beyond the driver experience: because drivers are free, there’s no monetization pressure forcing Pesly to fix poor retention — but the entire owner-side product depends on driver data actually flowing in (Section 41’s flywheel: more vehicles → more evidence → better reconciliation). Driver retention isn’t just a UX nicety here; it’s the input the whole reconciliation engine depends on, which is why it’s worth treating as a designed system rather than an assumed side-effect of the value proposition.

11. The Owner Product

The owner sees the fleet.

Fleet Overview

12 vehicles Revenue: KSh 84,200 Operating costs: KSh 31,700 Net contribution: KSh 52,500 Utilization: 74%

Attention required: [High] 2 revenue discrepancies [Medium] 3 cost anomalies [Maintenance] 2 maintenance concerns

Then drill into individual vehicles.

12. Owner-Driver Data Boundary

This is a fundamental product principle: **owners receive business intelligence, not unrestricted personal surveillance.**

Owners can see appropriate vehicle performance, revenue, expenses, utilization, operational metrics, and reconciliation issues. They don’t automatically receive personal movement history, unrestricted live location, personal financial information, or unrelated personal activity.

Privacy permissions are enforced by the backend, not merely hidden in the UI.

Enforcement mechanics — how the boundary actually holds under pressure:

- **Refuse by default, decide-with-visibility for the driver.** If an owner requests access beyond the default boundary (e.g. raw location), Pesly flags and declines the request automatically — but the final decision to grant an exception sits with the driver, not with Pesly or the owner. Critically, the refusal itself is a visible event: the driver sees “Owner requested raw location access on [date] — declined by default,” so they know Pesly is actively pushing back on their behalf rather than silently trusting the system.
- **Granular, scoped grants — never a blanket toggle.** If a driver chooses to grant an owner more access, it is scoped and time-bound (e.g. “share general-

ized location for today only”), not an all-or-nothing switch. This prevents one uncomfortable moment from becoming permanent overexposure.

- **Revocation must be as easy as granting.** Whatever access a driver grants can be revoked in one action, at any time. Asymmetry between “easy to give, hard to take back” is the kind of dark pattern that undermines the “protection” promise Pesly makes to drivers, and is something reviewers and regulators specifically look for.
-

13. The Agreement Engine

Pesly supports fixed daily arrangements, fixed weekly arrangements, percentage splits, hybrid arrangements, and custom agreements.

Each agreement has an effective date, vehicle, parties, calculation rules, expenses, exceptions, and version history.

If the agreement changes: a new agreement version is created — historical calculations are never overwritten.

14. The Financial Engine

The financial engine separates revenue, platform deductions, operating costs, owner allocation, and driver net earnings. This means Pesly can produce multiple legitimate views without changing the underlying financial events.

15. Maintenance

Pesly records the actual event — e.g. “four tyres purchased, KSh 24,000.” That fact does not change. But the system can display it two ways:

- **Cash accounting** — KSh 24,000 expense this month
- **Economic allocation** — cost distributed across expected useful mileage

This prevents manipulation while still supporting meaningful financial analysis.

16. Cash Trips

Cash is inherently harder to verify. Pesly displays:

Reported: KSh 900 Estimated range: KSh 780–900 Independent evidence:
None Status: Reported / unverified

Repeated anomalies trigger investigation. They do not automatically trigger accusations.

17. AI

Pesly's AI is not a generic chatbot. Its job is to understand → reconcile → explain → recommend.

The deterministic system calculates: KSh 5,240. The AI explains: "Your net earnings were 9% lower than your normal Wednesday because fuel costs increased while earnings per trip declined."

This architecture dramatically reduces hallucination risk.

18. AI Autonomy

- **Low risk (automatic):** summaries, categorization, reminders, trend detection
- **Medium risk (recommendation):** maintenance, expense investigation, operational changes
- **High risk (human approval required):** financial adjustments, contractual changes, adverse driver actions, fraud accusations, legal conclusions

Pesly does not allow AI to punish people.

19. Fraud and Anomaly Detection

Pesly detects patterns such as revenue inconsistencies, unusual fuel consumption, duplicate trips, unusual expenses, unexplained vehicle activity, repeated cash anomalies, and suspicious account behavior.

The language is always "This requires review" — never "Your driver stole money." That distinction is central to Pesly's neutrality.

20. Liability & Accountability Framework

Pesly's flags are evidence, not verdicts, and the plan treats this as a load-bearing legal principle rather than just a UX tone choice:

- **Pesly never asserts fact.** Every anomaly is phrased as "requires review." Pesly's role is limited to surfacing reconciled evidence — it does not conclude wrongdoing, and its outputs are not represented as proof of anything.
- **Responsibility sits with whoever acts on the output.** Pesly's Terms of Service will state plainly that if an owner takes action against a driver (financial, contractual, or otherwise) based on a Pesly flag, responsibility for that action sits with the owner, not with Pesly — the owner is expected to independently verify before acting, not treat a flag as a conclusion.

- **This is deferred in detail, not left blank.** A full legal liability framework (insurance, formal ToS drafting, dispute-resolution process) is not needed for the pilot stage, but the plan explicitly states the intended principle now so it isn't a visible gap when reviewed — and so the eventual ToS drafting has a clear starting position rather than starting from zero.
-

21. Privacy Strategy

Location data is minimized. Pesly should generally prefer “trip detected, 18.4 km, 42 minutes, generalized pickup/drop-off areas” over storing every GPS point for months.

The driver receives a Privacy Center showing what data is collected, why it is collected, who can access it, retention, permissions, and deletion/portability options where applicable.

Kenya's data-protection framework requires organizations processing personal data to comply with the relevant obligations, and the registration regulations specifically identify transport services as a category subject to registration.

So privacy isn't a marketing feature — it is core infrastructure.

22. Regulatory Position

This is an important strategic decision. Pesly should initially **not** be a ride-hailing marketplace, a passenger-driver matching service, a fare-setting platform, a passenger payment intermediary, or another transport network company.

Kenya's transport-network regulations impose licensing and operational requirements on entities that offer transport-network services.

Instead: **Pesly is an intelligence layer supporting people and businesses already using transport/delivery platforms.** That reduces unnecessary regulatory exposure during the initial phase.

A Kenyan legal/compliance review should still determine exactly how Pesly's specific integrations and data processing are classified before launch.

23. Data Protection Compliance

Pesly should plan from the beginning for: ODPC registration where applicable, privacy policy, data-processing agreements, consent/other lawful processing bases, data minimization, retention schedules, data-subject rights, access controls, security controls, breach procedures, and cross-border processing safeguards where relevant.

The ODPC registration process currently asks applicants to identify personal-data processing, safeguards, and organizational information.

24. Integration Strategy

Pesly shouldn't depend on one platform. Its connector architecture should support: **Platform → Normalized evidence → Pesly reconciliation.**

That means Uber, Bolt, delivery platforms, financial sources, and future providers can become connectors rather than separate products. Where official APIs or partnerships aren't available, Pesly uses only authorized, lawful data-access mechanisms (see Section 7.1) rather than relying on fragile scraping.

25. Offline-First

Kenyan connectivity conditions make this important. Pesly should support: **capture → store locally → sync later.**

This also reduces data costs, battery usage, and network dependence. The application should be lightweight enough that drivers don't feel it is consuming the resources they need to work.

25.5 Competitive Landscape

Three categories of existing alternative already serve pieces of this problem in Kenya. None of them do reconciliation across sources.

1. Driver-side expense trackers (closest direct competitor). RiderPal is an app built for Kenyan ride-hailing drivers to log expenses, see true profit, and grow their driving business, and was founded by an active ride-hailing driver who taught himself to code. It is a strong, credible product for what it does — but everything is manually logged by the driver, one entry at a time, with no independent evidence sources, no owner-facing product, and no cross-checking of what's reported against what platforms or M-Pesa actually show. It's a bookkeeping tool, not a reconciliation engine — the driver's own number is the only number in the system.

2. Telematics and fleet-tracking incumbents. Cartrack/Karooooo and Track-Always Africa's Venus platform serve Kenyan fleets with vehicle and driver monitoring, real-time location data, vehicle recovery, fuel-level sensor integration, driver-behaviour analysis, and route-compliance reporting. These are mature, well-funded products — but their center of gravity is *where the vehicle is and how it's driven*, not *what the vehicle earned*. They answer operational questions, not financial reconciliation questions, and they have no driver-side product at all — installing one is something done *to* a driver, which is exactly the “monitoring app” positioning Pesly is designed to avoid (Section 10).

3. Dispatch/fleet-operations software. Onde and similar white-label platforms give ride-hailing *operators* — companies trying to run their own Uber-style service

— order dispatch, driver apps, and payment processing. This targets a different customer entirely: someone building a ride-hailing business from scratch, not an individual owner or small fleet already using Uber, Bolt, or Little.

4. The actual status quo for most individual owners and small fleets: spreadsheets, WhatsApp groups, paper notebooks, and manually checking M-Pesa statements — which is the fragmentation problem described in Section 2, still unsolved for the majority of the target market.

What none of these do: take evidence from more than one source about the same trip or vehicle and reconcile it into a single trustworthy number, with a visible confidence status per figure (Section 8). RiderPal trusts the driver. Telematics trusts the sensor. Dispatch software trusts the operator’s own system. Pesly is the only one of the four that assumes any single source could be wrong and is built to check.

Adjacent players (not direct competitors, but worth knowing). Beyond Kenya’s mobility-app market, three broader players occupy nearby ground:

- **Argyle (US)** sells gig-worker income and employment data pulled directly from platforms like Uber and DoorDash to lenders and verification companies. It’s the closest conceptual match to Pesly’s evidence layer, but it’s B2B infrastructure for lenders — no driver or owner ever sees it directly — has no Africa presence, and pulls from a single platform per user rather than reconciling disagreeing sources.
- **Moove (Nigeria-founded, now global)** finances vehicles for ride-hailing drivers and underwrites the loan using the driver’s trip and revenue data from one ride-hailing platform (originally Uber). This is useful precedent — it proves platform earnings data can be trusted enough to base real financing decisions on — but it also demonstrates the exact risk Pesly’s multi-source design avoids: when Uber exited Nigeria in September 2026, it broke the single-platform data stream Moove had built its underwriting model on, since drivers could suddenly multi-app across Bolt and inDrive with no unified reporting underneath. This is a live, citable case for why reconciling across multiple sources — rather than trusting one platform — is the more resilient design choice.
- **Domestic gig-fintechs** (ImaliPay, Payday, and similar) give gig workers payments, BNPL, or lending APIs, but none do financial reconciliation of vehicle earnings specifically, and none focus on the Kenyan owner-driver dynamic.

The honest, defensible claim: not “no one has thought of this,” but that the pieces already exist separately — income-data aggregation, revenue-based underwriting, expense tracking, GPS telematics — and nobody combines them into a driver-owner reconciliation layer for the Kenyan market specifically.

26. Competitive Position

Pesly should not try to beat established telematics companies at GPS tracking, ride-hailing companies at ride matching, or accounting software at generic bookkeeping.

Its position is: **the reconciliation and intelligence layer between them.**

A GPS provider knows the vehicle traveled 18 km. A ride platform knows a trip generated KSh 820. M-Pesa knows KSh 820 was received. The driver knows KSh 300 fuel was purchased. **Pesly connects those pieces.**

27. The Moat

The long-term moat is **reconciled mobility data** — not an AI chatbot, not a dashboard, not GPS.

The more vehicles Pesly observes, the better it understands normal earnings, fuel patterns, trip economics, cost benchmarks, anomalies, vehicle utilization, and seasonal behavior. That creates a defensible intelligence layer.

27.5 Platform-Dependency & Copycat Risk

Platform dependency — a real, concrete technical risk, not a hypothetical one. Tier 1 acquisition (Section 7.1) depends on two things Pesly doesn't control: Uber/Bolt continuing to send parseable email statements, and Google Play continuing to permit M-Pesa SMS parsing under its SMS and Call Log Permissions policy. The second is worth stating plainly rather than assuming away: Google Play restricts the SMS-reading permission to apps registered as the user's default SMS handler, unless the app qualifies for a specific documented exception — and personal finance apps that parse bank/mobile-money SMS to auto-categorize transactions are a live, currently-approved exception category (several such apps are published and active on the Play Store today). The risk is real but manageable, not fatal: Google has specifically tightened scrutiny on apps in the Financial Services category over the past two years, meaning Pesly's Play Store submission needs the SMS-parsing feature clearly documented as core, disclosed functionality from day one, and the policy itself could tighten further at any time — exactly the kind of dependency that broke Moove's Nigerian underwriting model when Uber exited (Section 25.5). The mitigation is the same design principle already in Section 7.1: SMS parsing is one of three Tier 1 methods, not the only one, so a policy change degrades evidence quality for that one source rather than breaking the product outright.

Copycat risk — why a well-funded incumbent doesn't erase this once it's proven. If Pesly proves the reconciliation model works, the two most likely copiers are the platforms themselves (Uber/Bolt building owner-facing reconciliation) or a telematics incumbent (Cartrack, TrackAlways) adding an earnings layer. Both face a structural obstacle Pesly doesn't:

- **Uber/Bolt have a conflict of interest a neutral reconciler can't have.** Pesly's core value is flagging when a platform's reported number doesn't match independent evidence. A platform building that same feature would be grading its own homework — a driver has no reason to trust Uber's own tool to impartially flag discrepancies in Uber's own reported earnings, whereas Pesly's independence from any single platform is precisely what makes its flags

credible (Section 6). This isn't a speed advantage Pesly could lose to a faster competitor — it's a position only a neutral third party can occupy at all.

- **Telematics incumbents lack the trust position, not the engineering capacity.** Section 25.5 already notes they have no driver-facing product — installing one is something done *to* a driver. Bolting a financial reconciliation feature onto a monitoring tool doesn't fix that trust problem; it would need an entirely different driver relationship, which is a go-to-market problem, not a feature-parity one.
- **The moat compounds with time, which favors whoever starts first.** Section 27's benchmark data (normal earnings patterns, fuel-cost baselines, anomaly thresholds) gets better with every vehicle observed. A copier starting later isn't just behind on features — they're behind on the data that makes the reconciliation itself trustworthy, which is a harder gap to close quickly than rebuilding the UI.

What this doesn't solve: none of this is a permanent guarantee — a well-capitalized incumbent could still out-invest Pesly to close the trust and data gap over a long enough timeline. The honest claim is that Pesly has a multi-year structural head start, not an unbreachable moat, which is consistent with the plan's own principle of treating advantages as hypotheses to prove, not guarantees to assert (Section 48).

28. Target Market

Initial market: Kenyan ride-hailing and delivery vehicle ecosystem — individual vehicle owners, small fleets, multi-vehicle owners, driver-owner arrangements, and drivers working across multiple platforms.

Initial geographic focus: Nairobi, then Mombasa, Kisumu, Nakuru, and other major Kenyan mobility markets. Only after proving the Kenyan model should Pesly expand internationally.

29. Customer Segments

1. **Drivers** — acquisition engine
 2. **Individual owners** — early paying customer
 3. **Small fleets** — core commercial customer
 4. **Fleet operators** — higher-value customer
 5. **Larger mobility businesses** — later enterprise opportunity
-

30. Business Model

Drivers — free. Core features: trip tracking, earnings reconciliation, basic financial dashboard, personal history, privacy controls. This removes the biggest adoption barrier.

Owners — paid. Owner/fleet intelligence. Potential pricing structure (not finalized — to be derived from pilot economics):

- Starter: 1-3 vehicles
 - Growth: 4-20 vehicles
 - Fleet: 21-100 vehicles
 - Enterprise: 100+ vehicles
-

31. Future Revenue Streams

Once the core product works: premium driver intelligence (advanced analytics), fleet subscriptions (more vehicles, advanced reporting), enterprise integrations (API/data infrastructure), telematics partnerships (revenue share), maintenance ecosystem (qualified service-provider partnerships), and eventually financial products (financing, insurance, savings, vehicle loans) — but not in the MVP.

32. Why Drivers Shouldn't Be the Primary Revenue Source

If drivers pay from day one, the product risks becoming “another expense.” But if an owner pays because Pesly saves/discovers KSh 10,000/month, Pesly can charge a fraction of that value while the driver still gets the product free. That creates alignment.

33. The ROI Proposition

The owner isn't buying “fleet software” — they're buying **visibility into money leakage and vehicle profitability.**

Illustrative example: Pesly discovers KSh 5,000 unexplained revenue, KSh 3,000 excessive operating cost, and KSh 2,000 avoidable downtime — KSh 10,000 in identified value. A KSh 1,500-2,500 monthly subscription becomes much easier to justify. (These numbers are illustrative, not proposed final pricing.)

34. MVP

Driver: account, vehicle connection, trip detection, earnings, expenses, net earnings, corrections, disputes, privacy center

Owner: vehicle dashboard, revenue, expenses, net vehicle performance, utilization, anomalies, reconciliation

Backend: evidence engine, trip engine, ledger, agreement engine, reconciliation engine, permissions, audit trail

AI: explanations, summaries, anomaly explanations, recommendations

That's enough.

35. What We Deliberately DON'T Build in MVP

No passenger marketplace, ride booking, insurance, lending, fuel marketplace, maintenance marketplace, social network, driver recruitment marketplace, unrestricted live tracking, hardware manufacturing, or autonomous financial decisions.

This discipline is extremely important.

36. Go-to-Market Strategy

36.0 Owner Acquisition Channel

Kenya's mobility sector is already organized into groupable communities, which means owner acquisition doesn't have to start as one-by-one cold outreach:

- **Driver-led referral (the primary channel, and free).** Because drivers use Pesly free from day one, and many drivers work vehicles they don't own, the natural first sales motion is a driver showing their own owner the reconciled evidence Pesly already produced for them — "here's what Pesly shows for this car." This is the same flywheel already described in Section 41, applied specifically to acquisition rather than just data quality.
- **Existing associations and SACCOs.** Kenya has over 22,000 SACCOs, many organized specifically around vehicle owners (matatu SACCOs, boda boda SACCOs like those under the Kenya BodaBoda Association, and driver associations such as the Amalgamation of Digital Taxis Associations in Kenya). These groups already aggregate exactly the multi-vehicle owners Pesly's pricing tiers target (Section 30) and are a distribution channel worth approaching directly, rather than reaching owners one at a time.
- **The same WhatsApp groups used for validation.** The owner conversations planned for the survey stage aren't just research — they're the first warm leads. An owner who engages with the validation questions is already a qualified early pilot candidate.
- **Founder-led direct outreach for the pilot specifically.** At 10-20 vehicles (Stage 1), this is realistically a solo, hands-on sales motion — direct conversations, not a scaled channel — which matches the solo-founder stage honestly stated in Section 1.5.
- **Managed-fleet and leasing partners, as a later-stage channel.** Companies that already aggregate many vehicle owners under one relationship (e.g., dealerships running guaranteed-return investor schemes, or vehicle leasing operators) are a higher-leverage B2B2B channel once Pesly has pilot proof — one partnership could bring many vehicles at once, rather than one owner at a time. This is a Stage 3/4 channel, not an MVP dependency.

Stage 1 — Evidence Pilot

Start with approximately 10-20 vehicles, not hundreds.

Goal: determine whether Pesly can actually reconcile reality.

Measure: trip detection, revenue accuracy, expense completeness, reconciliation accuracy, battery consumption, data usage, driver retention.

Budget sketch (funded by grant/competition prize money):

Item	Purpose
Driver data/device stipends (10-20 drivers)	Cover SMS/data costs so the pilot doesn't cost drivers anything to participate
Founder/team runway for pilot duration	Time to build, observe, and iterate on reconciliation accuracy
Integration development buffer	Gmail-API and SMS-parsing build-out, plus the pre-build ToS/legal review in Section 7.1
Contingency	Unplanned issues — device replacement, extended pilot length, legal review follow-up

(Exact KSh figures should be filled in once you have concrete device/data unit costs and a target pilot length — but stating this breakdown, even directionally, turns “the grant funds the pilot” from an assertion into a plan a reviewer can evaluate.)

Stage 2 — Controlled Fleet Pilot

Expand to 50-100 vehicles with several different owner-driver arrangements: fixed daily, percentage, hybrid, different platforms, cash trips, different vehicle types. This tests whether Pesly survives real-world variation.

Stage 3 — Paid Pilot

Move selected fleets onto paid plans. Now measure: does the owner believe Pesly creates enough economic value to pay for it? This is where pricing is validated.

Stage 4 — Nairobi Launch

Once the following are proven (targets, not guarantees, to be set from pilot data): high-confidence trip detection, high reconciliation agreement, strong weekly driver retention, strong owner retention, and demonstrable ROI — then scale.

37. Key Success Metrics

North Star Metric: Reconciled Vehicle Value — the amount of vehicle economic activity Pesly can reliably reconcile and explain.

Data: trip detection accuracy, revenue reconciliation rate, expense capture rate

Driver: weekly active drivers, retention, net-earnings usage, dispute resolution usage

Owner: weekly active owners, vehicles managed, retention, anomalies investigated, ROI discovered

Business: MRR, ARPU, customer acquisition cost, gross margin, net revenue retention

38. The First-Year Roadmap

Q1 — Foundation: company formation, privacy/compliance architecture, evidence model, ledger, trip detection prototype, driver MVP, initial owner dashboard, ToS/legal review of acquisition methods (Section 7.1)

Q2 — Pilot: 10-20 vehicles, data collection, reconciliation testing, accuracy improvements, driver interviews, owner interviews

Q3 — Product validation: 50-100 vehicles, platform integrations, anomaly detection, agreement engine, paid pilot, ROI measurement

Q4 — Commercial launch: Nairobi launch, fleet sales, partnerships, pricing optimization, stronger integrations, expansion planning

39. Three-Year Vision

Year 1: Know what happened — reconciliation **Year 2:** Understand why — intelligence **Year 3:** Help optimize it — predictive recommendations and automation

Eventually: Pesly becomes the financial operating system for vehicle-based work.

40. The Long-Term Vision

The endgame isn't "another fleet app." It is **the financial intelligence infrastructure for Africa's mobility economy.**

A vehicle can move between Uber, Bolt, delivery platforms, private work, corporate work, multiple drivers, and multiple owners. Pesly remains the neutral financial layer across those relationships.

41. The Strategic Flywheel

Owner side: More vehicles → more evidence → better reconciliation → better intelligence → better recommendations → more financial value discovered → higher owner ROI → more fleets → more vehicles

Driver side: More drivers → better earnings visibility → more trust → portable work history → higher retention → more vehicles connected

These two flywheels meet at the vehicle.

42. The Biggest Strategic Risk

It isn't technology. It isn't competition. It's this: **Pesly collects a lot of information but fails to produce information that is materially better than what users already have.**

If that happens, Pesly becomes "another dashboard." We must avoid that at all costs.

43. The Product Test

Every major feature should answer: **does this improve Pesly's ability to understand what happened, explain why it happened, or help someone make a better decision?** If not, don't build it.

44. The Revised Company Positioning

One-line description: Pesly is an intelligent financial and operational platform that reconciles vehicle earnings, costs and activity into one trustworthy picture for drivers and fleet owners.

Driver promise: Know what you really earned. **Owner promise:** Know what your vehicle is really making. **Shared promise:** Replace arguments with evidence. **Technology promise:** Collect evidence → reconcile reality → explain it → create intelligence.

45. Why This Is a Much Stronger Business

The original concept could easily have become "GPS + AI + fleet dashboard" — crowded and relatively easy to copy.

The revised Pesly is **evidence infrastructure + financial reconciliation + operational intelligence** — substantially more defensible, with aligned incentives:

- Driver: "I get financial clarity and protection."

- Owner: “I get visibility and profitability.”
- Pesly: “I reconcile the evidence between them, and I’m accountable for what I claim to know versus what I flag for review” (see Section 20).

Nobody has to surrender their interests for the product to work.

46. The Final Business Model, in One Picture

47. The Decision Locked Now

Pesly is officially positioned as: **Pesly — Financial Intelligence for Vehicle-Based Work.**

Not fleet tracking. Not driver monitoring. Not ride-hailing. Not accounting software. Not an AI chatbot. **Financial intelligence.**

The initial wedge is **automated earnings + cost reconciliation.** Everything else grows from there.

48. One Final Reality Check

There is one thing this plan will not claim as a proven fact: **“Pesly will definitely save drivers/owners X%.”** We don’t know that yet.

The plan treats reconciliation accuracy, adoption, and ROI as **hypotheses the pilot must prove**, not inflated claims — which makes it more credible to an investor, grant panel, or early fleet customer.

The Kenyan regulatory environment also reinforces the decision to keep the first version out of passenger matching/ride-hailing itself: Kenya’s current regulations impose a licensing framework on transport network companies, including data-registration requirements.

49. Next Document

The next document to build from this is the **Pesly Master Product & Company Blueprint**: a single source of truth containing the business model, exact MVP, user journeys, database entities, system architecture, AI architecture, financial formulas, permissions, privacy rules, pricing assumptions, KPIs, pilot design, and 12-month build roadmap — enough to move directly from strategy into building Pesly.
